INTRODUCTION

Lipid solubility and molecular size are the major limiting factors for molecules to pass the biological membrane to be absorbed systematically following oral or topical administration. The effectiveness of any herbal product (or medication) is dependent upon delivering an effective level of the active compounds. Phytosomes are recently introduced advanced microsphere or cell forms of herbal products that are better absorbed, and produce better pharmacokinetic and pharmacodynamic profile than conventional herbal extracts. These are also known as herbosomes. The term "Phyto" means plant while "some" means cell-like. The phytosome structures contain the active ingredients of the standardized plant extract or its constituents bound to phospholipids, mainly phosphatidylcholine producing a lipid compatible molecular complex. Phospholipids are complex molecules that are used in all known life forms to make cell membranes. They are cell membrane building blocks, making up the matrix into which fit a large variety of proteins that are enzymes, transport proteins, receptors, and other biological energy converters. In humans and other higher animals the phospholipids are also employed as natural digestive aids and as carriers for both fat-miscible and water miscible nutrients. Phosphatidylcholine is not only a passive "carrier" for the bioactive flavonoids of the phytosomes, but is itself a bioactive nutrient for liver disease. Flavonoids (e.g., anthocyanidins from bilberry, catechins from green tea, silymarin from milk thistle) are the most bioactive constituents of phytomedicines. Poor absorption of many flavonoids is due to two factors. First, they are having multiple-ring molecules that are too large to be absorbed by simple diffusion. Secondly flavonoid molecules typically have poor miscibility with oils and other lipids, which limited their ability to pass across the lipid-rich outer membranes of the enterocytes of the small intestine. Water-soluble flavonoid molecules can be converted into lipid-compatible molecular complexes; aptly called phytosomes. The phospholipid molecular structure includes a water-soluble head and two fat-soluble tails. Because of this dual solubility, the phospholipid acts as an effective emulsifier. By combining the emulsifying action of the phospholipids with the standardized botanical extracts, the phytosome form provides dramatically enhanced bioavailability for lipid soluble drugs explained by faster and improved absorption in the intestinal tract. Phytosome protect the valuable components of the herbal extract from destruction by digestive secretions and gut bacteria. Phytosomes are used in the treatment of the acute and chronic liver disease of toxic metabolic or infective origin or of degenerative nature. It can also be used in anti-inflammatory activity as well as in pharmaceutical and cosmetic compositions. Silybin and the other silymarin flavonolignans from milk thistle conserve tissue glutathione, are liver-protective, and have anticancer potential. Curcumin and its related diphenolic curcuminoids have potent antioxidant, anti-inflammatory, and anti-carcinogenic properties. The green tea flavan-3-ol catechins have antioxidant, anti-inflammatory, cardio- and neuro-protective effects, and anti-carcinogenic benefits, with fat oxidation effects coupled to weight loss. The complex grape seed proanthocyanidin mix (including catechin and epicatechin monomers and oligomers) counters oxidative stress and protects the circulatory system (Table 1). For each of these preparations, conversion into phytosomes has improved efficacy without compromising safety. The first commercial Phytosome preparation was based on flavonolgenan Silybin the major constituent of silymarin, a flavon complex extracted from milk chistle fruit (silybum marianum, family Asteraceae/ Compositae). This phytosome preparation was initially christened IDB 1016 or Silipide and subsequently recasts as Silipos® Phytosome®. Silybin phosphatidylcholine is clinically validated for its anti-inflammatory, antioxidant and liver detoxification benefits.

Difference between phytosome and liposome

The fundamental difference between liposomes and phytosomes is that in liposomes the active principle is dissolved in the medium contained in the cavity or in the layers of the membrane, whereas in the phytosome it is an integral part of the membrane, being the molecules anchored through chemical bonds to the polar head of the phospholipid (Fig 1). Liposomes are used primarily in cosmetics to deliver water-soluble substances to the skin. A liposome is formed by mixing a water-soluble substance with phosphatidylcholine. No chemical bond is formed; the phosphatidylcholine molecules surround the water-soluble substance. There may be hundreds or even thousands of phosphatidylcholine molecules surrounding the water-soluble compound. In contrast, with the Phytosome process the phosphatidylcholine and the individual plant components actually from a 1:1 or a 2:1 complex depending on the substance. This difference results in Phytosomes being much better absorbed that liposomes. Phytosomes are superior to liposomes in skin care products.

Advantages of phytosomes

As compared to conventional herbal formulation, phytosomes have following advantages.

1. They enhance the absorption of lipid insoluble polar botanical extract through oral as well as topical route showing better bioavailability, hence significantly greater therapeutic benefit.
2. As the absorption of active constituent(s) is improved, its small dose can produce desired results.
3. Phosphatidylcholine used in preparation of phytosomes, besides acting as a carrier also acts as a hepatoprotective,
Advances in phytosome technology

In a very recent study the tissue and blood effects of high-dose silybin-phytosome in prostate cancer patients was determined. Patients received silybin-phytosome for 14-31 days (mean was 20 days) prior to surgery. Sildinin blood levels were measured 1 h after the first silybin-phytosome dose with a mean value of 19.7 µM. One of the treated patients developed a grade 4 post-operative thromboembolic event. The other observed toxicities in the treatment group were mild: four subjects had diarrhoea and one had asymptomatic grade 2 hyperbilirubinemia which was transient. The results indicate that high-dose oral silybin-phytosome achieves high blood concentrations transiently, but low levels of sildinin are seen in prostate tissue.

Formulation of phytosomes

Phytosomes are prepared by reacting the herbal extract in an aprotic solvent such as methylene chloride, dioxane and ethyl acetate with the phospholipid such as phosphatidylcholine, phosphatidylethanolamine or phosphatidylserine dissolved in the same solvent. After solubilization has been completed, the complex compounds are isolated by removing the solvent under vacuum, by freeze drying or by precipitation with non solvents such as n-hexane. Thus the obtained complexes are lipophilic in character and soluble in a polar and aprotic solvent, in which the individual components of the complex are normally insoluble.

Green Phytosome were prepared and studied in 100 obese subjects (both male and female, divided into 2 groups of 50 each). Group 1 was given hypocaloric diet with green tea phytosome. Group 2 was given only hypocaloric diet. After 90 days, parameters like weight, body mass index, low density lipid, high density lipid, total cholesterol, triglycerides, growth factor, cortisol were determined. All parameters were improved in both groups but there was more weight loss in green tea phytosome group than in diet only group (14 kg loss versus 5 kg loss). Also, no adverse effects were reported during and after trial.6

Another method currently being investigated is complexing curcumin with a phospholipid, known as a phytosome. The phosphatidylcholine-curcumin complex (Meriva®) is more readily...
incorporated into lipophilic cell membranes, making it significantly more bioavailable than unbound curcumin. In rats, peak plasma concentration and AUC were five times higher for Meriva than for unbound curcumin14.

Phytosomes of curcumin (flavonoid from turmeric, Curcuma longa) and naringenin (flavonoid from grape fruit, vitis vinifera) showed higher antioxidant activity than pure curcumin in all dose levels tested16. In a study the bioavailability of silybin in rats was found to increase remarkably after oral administration of prepared silybin-phospholipid complex Phytosome due to an impressive improvement of the lipophilic property of silybin-phospholipid complex and improvement of the biological effect of silybin16.

Ginkgo biloba phytosome treatment was found to increase superoxide dismutase, catalase, glutathione peroxidase and glutathione reductase activities in all the brain regions compared with those treated only with sodium nitrite. Ginkgo biloba phytosomes were administered to Wistar rats at 50 mg/kg and 100 mg/kg for 7 and 14 days. Chemical hypoxia was induced by administration of sodium nitrite (75 mg/kg) 1 h after the last administration of treatment. Thirty minutes after sodium nitrite administration, the animals were killed and the cerebral cortex, cerebellum, hippocampus and striatum were isolated and homogenized. The supernatants were used for the estimation of the antioxidant enzymes superoxide dismutase, catalase, glutathione peroxidase and glutathione reductase17.

Herba Epimedi flavonoid phytosomes (EPF) were prepared by means of solvent evaporation technique and the accumulative dissolution of different ratios of EPF-PVP precipitates was investigated by means of dissolution release. For optimized preparation solvent-tetrahydrofurain, lecithin to PVP 2.5 times, temperature 40 °C and reaction 3 h. Oil/water apparent partition coefficient of icarin was enhanced more than 4 times by phospholipid. The accumulative dissolution of Herba Epimedi flavonoids of EPF-PVP precipitate was significantly higher than that of its physical mixture and Herba Epimedi extract tablet15.

Patients suffering from chronic hepatitis (viral, alcohol or drug induced) treated with silybin phytosome at a dose of 120 mg either twice daily or thrice daily for up to 120 days, liver function returned to normal faster in patients taking silybin phytosome compared to a group of controls (49 treated with commercially available silymarin, 117 untreated or given placebo)17.

In a study silymarin (a standardized mixture of flavonolignans extracted from the fruits of S. marianum) phytosomes showed much higher specific activity and a longer lasting action than the single constituents, to percent reduction of edema and inhibition of myeloperoxidase activity20.

A human study was conducted to design the absorption profile of silybin when directly bound to phosphatadylcholine. Plasma levels of silybin were determined after administration of single oral doses of silybin phytosome and a similar amount of silybin from milk thistle in healthy volunteers. The results indicated that the absorption of silybin from silybin phytosome was approximately seven times greater compared to the absorption of silybin from regular milk thistle extract21.

**CONCLUSION**

Thorough study of literature different phytosome products has demonstrated significant therapeutic or health promoting properties when compared with the conventional plant extracts. Phytosomes can be developed for different therapeutic purposes like hepatoprotective, cardiovascular, liver diseases, anti-inflammatory, immunomodulator, anticancer, anti-diabetic etc or for prophylactic and health purposes as nutraceuticals, in due course.
