INTRODUCTION

The herbal medicines are recognized as most reliable, and cost effective than any other system of medicinal practice. In addition, the use of higher plants and their preparation to treat infectious and non-infectious diseases is an age old practices and are the only method available in the past. Plants which constitute an active part of the ecosystem have been found to be useful to man both as the use of higher plants and their preparation to treat infectious and non-infectious diseases is an age old practice. In addition, the herbal medicines are recognized as most reliable, and cost effective than any other system of medicinal practice. In addition, the use of higher plants and their preparation to treat infectious and non-infectious diseases is an age old practices and are the only method available in the past. Plants which constitute an active part of the ecosystem have been found to be useful to man both as sources of foods and medicine. Hence in many parts of the world, medicinal plants have continued to be an integral part of human civilization, the scientific analysis of different natural sources for their potential medicinal potency is of the health care system and the people’s culture. Though the use of natural sources like comparatively recent origin. The emergence and spread of antibiotic resistant microorganisms also triggered this type of plant investigations. Antibiotics are a class of antimicrobial agents. Antibiotics act by inhibition of cell wall synthesis, inhibition of folate metabolism and also binding to ribosomes to prevent translation and interference with nucleic acid synthesis. Higher plants can serve both as potential antimicrobial crude drugs as well as source of new anti-infective agents. The study species, Acalypha fruticosa Forsk., an erect woody shrub, belongs to the family, Euphorbiaceae is one such folklore plant used in traditional system of medicine in Coimbatore district of Tamil Nadu, India. It is distributed up to 1800m above msl in southern Western Ghats. This plant species has been used as a folk remedy for the treatment of dyspepsia, skin complaints, jaundice, cholera, sexually transmitted diseases, stomach problems, antipyretic and even as an antibiotic. The stem part of this species is used to heal wounds in animals and also used to treat toothache and the stem is used as fuel wood by tribal people. Despite these uses, no published works are available for the antimicrobial property of stem part of this plant. Hence in the present study, an attempt has been made to focus the plant in this angle and hence to assess its therapeutic potency.

MATERIALS AND METHODS

Plant material

Fresh stem parts were collected from the population of A. fruticosa present in the Marathamalai Hills of Coimbatore District and washed under running tap water, air dried and then homogenized to fine powder and stored in air tight bottles.

Preparation of extracts

250g air-dried stem powder was subjected to 250ml of methanol in soxhlet extraction for 8 hours (50-85°C). The extract was concentrated to dryness in a flask evaporator under reduced pressure and controlled temperature (50-60°C) to yield crude residue, which was then stored in refrigerator. To obtain petroleum ether and ethyl acetate extracts, the same method was adopted as used to obtain methanol extract.

Media used

Freshly prepared nutrient agar medium and PDA medium were used for the culture of bacteria and fungi respectively.

Microorganisms

In vitro antimicrobial activity was examined for the chemical extracts of stem part of the species, Acalypha fruticosa against ten bacterial species which include the gram positive strains viz., Micrococcus sp., Lactobacillus sp., Bacillus subtilis, Escherichia coli and gram negative strains viz., Pseudomonas aeruginosa, Staphylococcus aureus, Proteus vulgaris, Salmonella typhi, Shigella flexneri, Aeromonas hydrophila, Bacillus subtilis, Escherichia coli, Klebsiella pneumoniae, and Pseudomonas. All these microorganisms were obtained from the Department of Microbiology, Tamil Nadu Agricultural University, Coimbatore. All the microorganisms were maintained at 4°C on nutrient agar slants (for bacteria) and PDA slants (for fungi) until further use.

Antimicrobial assay

The alcoholic extracts were tested for their effect against the growth of pathogenic bacteria and fungi by disc diffusion method. Both the organisms, bacteria and fungi tested were inoculated into nutrient agar and PDA media respectively. After an incubation period of 24 hrs at a temperature of 35°C, three or four colonies isolated from these media were inoculated into 4ml of nutrient broth and incubated for 2 hrs at 35°C. The cultures were adjusted with sterile saline solution to obtain turbidity. Petri dishes containing Mueller-Hinton agar medium and PDA medium were streaked separately with these microbials suspensions of bacteria and fungi respectively. Disks of 6mm diameter were impregnated with the extracts of petroleum ether, methanol and ethyl acetate separately. Tetracycline is used as positive control. After equilibrium at 4°C, the plates were incubated overnight at 37°C and the diameter of any resulting zones of inhibition was measured. Each experiment was repeated at least three times.

RESULTS AND DISCUSSION

The results of the antimicrobial study report that all the three alcoholic extracts of the stem part of A. fruticosa generally showed...
significant activity against the growth of the colonies of ten bacteria tested (Pseudomonas aeruginosa, P. stutzeri, Escherichia coli, Micrococcus sp., Lactobacillus sp., Serratia sp., Moraxaeta sp., Bacillus subtilis, B. thuringiensis and Klebsiella pneumoniae). Among the three extracts, the ethyl acetate extract has determined to have highest inhibitory activity (32.67 mm diameter inhibitory zone) against the bacterium, Bacillus subtilis (gram positive) followed by the methanol extract against the same bacterium, (12.17 mm diameter inhibitory zone). It is explained that the different phytochemicals like steroids, cardiac glycosides, anthraquinone, flavonoids and phenolics extracted by using different solvents may be responsible for their antibacterial effects. Plants contain chemical substances that take part in the metabolic activities thereby helping to fight the bacterial infections. Amongst the gram-positive and gram-negative bacteria, the former bacterial strains were determined to be more susceptible to the extracts when compared to the later. This may be explained that the variation in structure of cell wall components between these two groups may cause this response. In addition, it has been explained that the ability of tannin compounds to cause the bacterial colonies to disintegrate, probably results from their interference with the bacterial cell wall; thereby inhibiting the microbial growth. It has been observed further that the ethyl acetate extracts showed significantly higher inhibitory activity against the colonial growth of Bacillus subtilis than that of the commercially available antibiotic, the tetracycline. This fact shows the higher therapeutic potential of ethyl acetate extract of the study species, A. fruticosa. The petroleum ether extract has comparatively less activity against the most of the tested bacteria. It may be attributed to the absence of respective active principle compounds or present with insufficient quantities in this crude extract.

The antifungal activity of various extracts of stem part of the species, A. fruticosa against the ten studied fungal species showed the following results: As shown in antibacterial activity, the ethyl acetate extract has the highest inhibitory activity (30.87 mm diameter inhibitory zone) against the fungus, Rhizopus sp. followed by methanol extract (14.83 mm diameter inhibitory zone) against the fungus, F. solani, and petroleum ether extract (12.87 mm diameter inhibitory zone) against the fungus, Cladosporium sp. This fact indicates the existence of strong antifungal activity of stem part of the study species, A. fruticosa and hence its effective healing property against the infectious diseases caused by fungal species. Presence of high amount of different flavonoids which has the antifungal property in the study species, A. fruticosa may be the possible reason for this fact. The variation in antifungal activity across the extracts studied may be due to the polarity of the solvents used and hence the ingredients present. Significantly higher inhibitory activity of ethyl acetate extract than the commercially available antibiotic tetracycline against the fungus, Rhizopus sp. showed the superior healingness of the stem part of the species, A. fruticosa. Therefore proper isolation and purification of active compounds by using ethyl acetate solvent would ensure the therapeutic value of this folkloric medicinal plant when it will be used commercially.

The present investigation on antimicrobial activity reports that the study species, A. fruticosa contains adequate variety of active principle compounds to reduce or check the growth of microbial colonies. It confirms the therapeutic value and hence the traditional usage of the stem part of the study species, A. fruticosa against various ailments. Further, these findings may lead support to the traditional use of A. fruticosa in the treatment of microbial infections. Further studies are recommended to purify the active compounds for the formulation of new drugs, while go for commercialization.
